Superplastic forming is a specialized metalworking process that allows sheets of metal alloys such as aluminum to be stretched to lengths over ten times that of conventional alloys without degrading the material properties of the metal. The process allows for the manufacture of complex metal parts, which eliminates the need for bolts and fasteners to attach individual metal parts together into a larger unit.

In materials science, superplasticity is a state in which solid crystalline material is deformed well beyond its usual breaking point, usually over about 600% during tensile deformation. Such a state is usually achieved at high homologous temperature. Examples of superplastic materials are some fine-grained metals and ceramics.
